--------------	-----------

author	<i>Author dataset</i>
--------	-----------------------

Description

This data matrix contains the counts of the 26 letters of the alphabet (columns of matrix) for 12 different novels (rows of matrix). Each row contains letter counts in a sample of text from each work, excluding proper nouns.

Usage

```
data("author")
```

Format

Data frame containing the 12 x 26 matrix.

Source

Larsen, W.A. and McGill, R., unpublished data collected in 1973.

ca	<i>Simple correspondence analysis</i>
----	---------------------------------------

Description

Computation of simple correspondence analysis.

Usage

```

ca(obj, ...)

## S3 method for class 'matrix'
ca(obj, nd = NA, suprow = NA, supcol = NA,
    subsetrow = NA, subsetcol = NA, ...)

## S3 method for class 'data.frame'
ca(obj, ...)

## S3 method for class 'table'
ca(obj, ...)

## S3 method for class 'xtabs'
ca(obj, ...)

## S3 method for class 'formula'
ca(formula, data, ...)

```

Arguments

obj, formula	The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" or "table" and one-sided formulae of the form $\sim F1 + F2$, where F1 and F2 are factors.
nd	Number of dimensions to be included in the output; if NA the maximum possible dimensions are included.
suprow	Indices of supplementary rows.
supcol	Indices of supplementary columns.
subsetrow	Row indices of subset.
subsetcol	Column indices of subset.
data	A data frame against which to preferentially resolve variables in the formula
...	Other arguments passed to the <code>ca.matrix</code> method

Details

The function `ca` computes a simple correspondence analysis based on the singular value decomposition.

The options `suprow` and `supcol` allow supplementary (passive) rows and columns to be specified. Using the options `subsetrow` and/or `subsetcol` result in a subset CA being performed.

Value

sv	Singular values
nd	Dimension of the solution

rownames	Row names
rowmass	Row masses
rowdist	Row chi-square distances to centroid
rowinertia	Row inertias
rowcoord	Row standard coordinates
rowsup	Indices of row supplementary points
colnames	Column names
colmass	Column masses
coldist	Column chi-square distances to centroid
colinertia	Column inertias
colcoord	Column standard coordinates
colsup	Indices of column supplementary points
N	The frequency table

# some plot options
plot(haireye.ca, lines=TRUE)
plot(haireye.ca, arrows=c(TRUE, FALSE))
```

caconv

Converting data types in CA and MCA

Description

Conversion from and to a number of different data types commonly used in CA and MCA (frequency tables, response pattern matrices, indicator matrices and Burt matrices).

Usage

```
caconv(x, from = c("freq", "rpm", "ind", "Burt"), to = c("rpm", "ind", "Burt", "freq"),
       nlev = NA, vars = c(1,2), ...)
```

Arguments

x	A matrix (two-way frequency table, indicator matrix, or Burt matrix) or data frame (response pattern matrix).
from	The type of input data in x: a frequency table ("freq"), or a response pattern matrix ("rpm"), or an indicator matrix ("ind"), or a Burt matrix ("Burt").
to	The data type into which x should be converted.
nlev	A vector containing the number of levels for each categorical variable (for from="ind" or from="Burt"). If NA, nlev is computed from the data.
vars	A vector of length 2 specifying the index of the variables to use for converting to "freq" (i.e. to a regular two-way frequency table).
...	Further arguments (ignored).

Details

The function caconv converts between data types in CA and MCA. Note that a conversion from from="Burt" to to="ind" or to="rpm" is not supported.

Value

A matrix or data frame containing the converted data (with the type specified in to).

[ca,mjca](#)

cacoord *Extracting coordinates from ca and mjca objects.*

Description

Extracting standard and principal coordinates as well as various row and column scaling configurations for visual display from ca and mjca objects.

Usage

```
cacoord(obj,
        type = c("standard", "principal",
                 "symmetric", "rowprincipal", "colprincipal", "symbiplot",
                 "rowgab", "colgab", "rowgreen", "colgreen"),
        dim = NA,
        rows = NA,
        cols = NA,
        ...)
```

Arguments

obj	A ca or mjca object returned by ca or mjca .
type	The type of coordinates to extract ("standard" or "principal"). The remaining options ("symmetric", ..., "colgreen") return the corresponding row/column coordinate configuration for the map scaling options described in plot.ca where the corresponding argument is map.
dim	The dimensions to return. If NA, all available dimensions are returned.
rows	Logical indicating whether to return the row coordinates (see below for details).
cols	Logical indicating whether to return the column coordinates (see below for details).
...	Further arguments (ignored).

Details

The function cacoord returns the standard or principal coordinates of a CA or MCA solution. Additionally, row and column scaling configurations for plotting methods can be computed (see [plot.ca](#) for details).

Note that by default row and column coordinates are computed (i.e. for (rows=NA&cols=NA) | (rows=TRUE&cols=TRUE)). Using rows=TRUE (and cols=NA or cols=FALSE) returns a matrix with the row coordinates, and for cols=TRUE (and cols=NA or cols=FALSE) a matrix with the column coordinates is returned.

Value

A list with the slots rows (row coordinates) and columns (column coordinates). When computing only row or only column coordinates, a matrix (with the corresponding row or column coordinates) is returned.

`iterate.mjca`*Updating a Burt matrix in Joint Correspondence Analysis*

Description

Updating a Burt matrix in Joint Correspondence Analysis based on iteratively weighted least squares.

Usage

```
iterate.mjca(B, lev.n, nd = 2, maxit = 50, epsilon = 0.0001)
```

Arguments

<code>B</code>	A Burt matrix.
<code>lev.n</code>	The number of levels for each factor from the original response pattern matrix.
<code>nd</code>	The required dimensionality of the solution.
<code>maxit</code>	The maximum number of iterations.
<code>epsilon</code>	A convergence criterion for the maximum absolute difference of updated values compared to the previous values. The iteration is completed when all differences are smaller than epsilon.

Details

The function `iterate.mjca` computes the updated Burt matrix. This function is called from the function `mjca` when the option `lambda="JCA"`, i.e. when a Joint Correspondence Analysis is performed.

Value

<code>B.star</code>	The updated Burt matrix
<code>crit</code>	Vector of length 2 containing the number of iterations and epsilon

See Also[mjca](#)

mjca

*Multiple and joint correspondence analysis***Description**

Computation of multiple and joint correspondence analysis.

Usage

```

mjca(obj, ...)

## S3 method for class 'data.frame'
mjca(obj, ...)
## S3 method for class 'table'
mjca(obj, ...)
## S3 method for class 'array'
mjca(obj, ...)

## Default S3 method:
mjca(obj, nd = 2, lambda = c("adjusted", "indicator", "Burt", "JCA"),
      supcol = NA, subsetcat = NA,
      ps = ":", maxit = 50, epsilon = 0.0001, reti = FALSE, ...)

```

Arguments

obj	A response pattern matrix (data frame containing factors), or a frequency table (a “table” object) or an integer array.
nd	Number of dimensions to be included in the output; if NA the maximum possible dimensions are included.
lambda	Gives the scaling method. Possible values include “indicator”, “Burt”, “adjusted” and “JCA”. Using lambda = “JCA” results in a joint correspondence analysis using iterative adjustment of the Burt matrix in the solution space. See Details for descriptions of these options.
supcol	Indices of supplementary columns.
subsetcat	Indices of subset categories (previously subsetcol).
ps	Separator used for combining variable and category names.
maxit	The maximum number of iterations (Joint Correspondence Analysis).
epsilon	A convergence criterion (Joint Correspondence Analysis).
reti	Logical indicating whether the indicator matrix should be included in the output.
...	Arguments passed to mjca.default

Details

The function `mjca` computes a multiple or joint correspondence analysis based on the eigenvalue decomposition of the Burt matrix. The `lambda` option selects the scaling variant desired for reporting inertias.

- `lambda="indicator"` gives multiple correspondence analysis based on the correspondence analysis of the indicator matrix, with corresponding inertias (eigenvalues).
- `lambda="Burt"` gives the version of multiple correspondence analysis based on the correspondence analysis of the Burt matrix, the inertias of which are the squares of those for the indicator option.
- `lambda="adjusted"` is the default option, giving improved percentages of inertia based on fitting the off-diagonal submatrices of the Burt matrix by rescaling the multiple correspondence analysis solution. All these first three options give the same standard coordinates of the categories.
- `lambda="JCA"` gives a joint correspondence analysis, which uses an iterative algorithm that optimally fits the off-diagonal submatrices of the Burt matrix. The JCA solution does not have strictly nested dimensions, so the percentage of inertia explained is given for the whole solution of chosen dimensionality, not for each dimension, but this percentage is optimal.

Value

<code>sv</code>	Eigenvalues (<code>lambda = "indicator"</code>) or singular values (<code>lambda = "Burt"</code> , <code>"adjusted"</code> or <code>"JCA"</code>)
<code>lambda</code>	Scaling method
<code>inertia.e</code>	Percentages of explained inertia
<code>inertia.t</code>	Total inertia
<code>inertia.et</code>	Total percentage of explained inertia with the <code>nd</code> -dimensional solution
<code>levelnames</code>	Names of the factor/level combinations, joined using <code>ps</code>
<code>factors</code>	A matrix containing the names of the factors and the names of the factor levels
<code>levels.n</code>	Number of levels in each factor
<code>nd</code>	User-specified dimensionality of the solution
<code>nd.max</code>	Maximum possible dimensionality of the solution
<code>rownames</code>	Row names
<code>rowmass</code>	Row masses
<code>rowdist</code>	Row chi-square distances to centroid
<code>rowinertia</code>	Row inertias
<code>rowcoord</code>	Row standard coordinates
<code>rowpcoord</code>	Row principal coordinates
<code>rowctr</code>	Row contributions
<code>rowcor</code>	Row squared correlations
<code>colnames</code>	Column names
<code>colmass</code>	Column masses

coldist	Column chi-square distances to centroid
colinertia	Column inertias
colcoord	Column standard coordinates
colpcoord	Column principal coordinates
colctr	column contributions
colcor	Column squared correlations
colsup	Indices of column supplementary points (of the Burt and Indicator matrix)
subsetcol	Indices of subset columns (subsetcat)
Burt	Burt matrix
Burt.upd	The updated Burt matrix (JCA only)
subinertia	Inertias of sub-matrices
JCA.iter	Vector of length two containing the number of iterations and the epsilon (JCA only)
indmat	Indicator matrix if reti was set to TRUE
call	Return of match.call

multilines

Draw lines for groups distinguished by a factor

Description

This is a convenience function for drawing a set of lines distinguished by the levels of a factor. It can be used to make more attractive plots than available via `plot.mjca`.

Usage

```
multilines(XY, group=NULL, which=1:nf, sort=1, type='l', col=palette(), lwd=1, ...)
```

Arguments

<code>XY</code>	A two-column data frame or matrix
<code>group</code>	A factor; a separate line is drawn for each level included in which
<code>which</code>	An integer vector used to select the factors for which lines are drawn. By default, all lines are drawn.
<code>sort</code>	Column of <code>XY</code> to sort upon before drawing the line for each group
<code>type</code>	Line type: "l" for line, "b" for line and points
<code>col</code>	A vector of colors to be used for the various lines, in the order of the levels in group; recycled as necessary.
<code>lwd</code>	A vector of line widths to be used for the various lines; recycled as necessary
<code>...</code>	Other graphic parameters passed to <code>lines</code> , e.g., <code>lty</code>

Value

none

Plotting 2D maps in correspondence analysis

Description

Graphical display of correspondence analysis results in two dimensions

Usage

```
## S3 method for class 'ca'
plot(x, dim = c(1,2), map = "symmetric", what = c("all", "all"),
     mass = c(FALSE, FALSE), contrib = c("none", "none"),
     col = c("blue", "red"),
     pch = c(16, 21, 17, 24),
     labels = c(2, 2),
     arrows = c(FALSE, FALSE),
     lines = c(FALSE, FALSE),
     lwd=1,
     xlab = "_auto_", ylab = "_auto_",
     col.lab = c("blue", "red"), ...)
```

Arguments

x	Simple correspondence analysis object returned by <code>ca</code>
dim	Numerical vector of length 2 indicating the dimensions to plot on horizontal and vertical axes respectively; default is first dimension horizontal and second dimension vertical.
map	Character string specifying the map type. Allowed options include "symmetric" (default), "rowprincipal", "colprincipal", "symbiplot", "rowgab", "colgab", "rowgreen", "colgreen"
what	Vector of two character strings specifying the contents of the plot. First entry sets the rows and the second entry the columns. Allowed values are "all" (all available points, default), "active" (only active points are displayed), "passive" (only supplementary points are displayed), "none" (no points are displayed). The status (active or supplementary) of rows and columns is set in <code>ca</code> using the options <code>suprow</code> and <code>supcol</code> .

mass	Vector of two logicals specifying if the mass should be represented by the area of the point symbols (first entry for rows, second one for columns)
contrib	Vector of two character strings specifying if contributions (relative or absolute) should be represented by different colour intensities. Available options are "none" (contributions are not indicated in the plot), "absolute" (absolute contributions are indicated by colour intensities), "relative" (relative contributions are indicated by colour intensities). If set to "absolute" or "relative", points with zero contribution are displayed in white. The higher the contribution of a point, the closer the corresponding colour to the one specified by the col option.
col	Vector of length 2 specifying the colours of row and column point symbols, by default blue for rows and red for columns. Colours can be entered in hexadecimal (e.g. "\#FF0000"), rgb (e.g. rgb(1, 0, 0)) values or by R-name (e.g. "red").
pch	Vector of length 4 giving the type of points to be used for row active and supplementary, column active and supplementary points. See pchlist for a list of symbols.
labels	Vector of length two specifying if the plot should contain symbols only (0), labels only (1) or both symbols and labels (2). Setting labels to 2 results in the symbols being plotted at the coordinates and the labels with an offset.
arrows	Vector of two logicals specifying if the plot should contain points (FALSE, default) or arrows (TRUE). First value sets the rows and the second value sets the columns.
lines	Vector of two logicals specifying if the plot should join the points with lines (FALSE, default) or arrows (TRUE). First value sets the rows and the second value sets the columns.
lwd	Line width for arrows and lines
xlab, ylab	Labels for horizontal and vertical axes. The default, "_auto_" means that the function auto-generates a label of the form Dimension X (xx.xx %
col.lab	Vector of length 2 specifying the colours of row and column point labels
...	Further arguments passed to plot and points .

Details

The function `plot.ca` makes a two-dimensional map of the object created by `ca` with respect to two selected dimensions. By default the scaling option of the map is "symmetric", that is the so-called *symmetric map*. In this map both the row and column points are scaled to have inertias (weighted variances) equal to the principal inertia (eigenvalue or squared singular value) along the principal axes, that is both rows and columns are in principal coordinates. Other options are as follows:

- "-rowprincipal" or "colprincipal" - these are the so-called *asymmetric maps*, with either rows in principal coordinates and columns in standard coordinates, or vice versa (also known as row-metric-preserving or column-metric-preserving respectively). These maps are biplots;
- "-symbiplot" - this scales both rows and columns to have variances equal to the singular values (square roots of eigenvalues), which gives a symmetric biplot but does not preserve row or column metrics;

- `-"rowgab"` or `-"colgab"` - these are asymmetric maps (see above) with rows (respectively, columns) in principal coordinates and columns (respectively, rows) in standard coordinates multiplied by the mass of the corresponding point. These are also biplots and were proposed by Gabriel & Odoroff (1990);
- `-"rowgreen"` or `-"colgreen"` - these are similar to `-"rowgab"` and `-"colgab"` except that the points in standard coordinates are multiplied by the square root of the corresponding masses, giving reconstructions of the standardized residuals.

This function has options for sizing and shading the points. If the option `mass` is `TRUE` for a set of points, the size of the point symbol is proportional to the relative frequency (mass) of each point. If the option `contrib` is `"absolute"` or `"relative"` for a set of points, the colour intensity of the point symbol is proportional to the absolute contribution of the points to the planar display or, respectively, the quality of representation of the points in the display. To globally resize all the points (and text labels), use `par("cex"=)` before the plot.

Value

In addition to the side effect of producing the plot, the function invisibly returns the coordinates of the plotted points, a list of two components, with names `rows` and `cols`. These can be used to further annotate the plot using base R plotting functions.

# Since the arguments are recycled it is sufficient to give only one argument
# for mass and contrib.
data("author")
plot(ca(author), what = c("none", "all"), mass = TRUE, contrib = "relative")
```

Description

Graphical display of multiple and joint correspondence analysis results in two dimensions

Usage

```
## S3 method for class 'mjca'
plot(x, dim = c(1,2), map = "symmetric", centroids = FALSE,
      what = c("none", "all"), mass = c(FALSE, FALSE),
      contrib = c("none", "none"), col = c("#000000", "#FF0000"),
      pch = c(16, 1, 17, 24),
      labels = c(2, 2), collabels = c("both", "level", "factor"),
      arrows = c(FALSE, FALSE), xlab = "_auto_", ylab = "_auto_", ...)
```

Arguments

x	Multiple or joint correspondence analysis object returned by mjca
dim	Numerical vector of length 2 indicating the dimensions to plot on horizontal and vertical axes respectively; default is first dimension horizontal and second dimension vertical.
map	Character string specifying the map type. Allowed options include "symmetric" (default), "rowprincipal", "colprincipal", "symbiplot", "rowgab", "colgab", "rowgreen", "colgreen"
centroids	Logical indicating if column centroids should be added to the plot
what	Vector of two character strings specifying the contents of the plot. First entry sets the rows and the second entry the columns. Allowed values are "all" (all available points, default), "active" (only active points are displayed), "passive" (only supplementary points are displayed), "none" (no points are displayed). The status (active or supplementary) of columns is set in mjca using the option <code>supcol</code> .
mass	Vector of two logicals specifying if the mass should be represented by the area of the point symbols (first entry for rows, second one for columns)

contrib	Vector of two character strings specifying if contributions (relative or absolute) should be represented by different colour intensities. Available options are "none" (contributions are not indicated in the plot). "absolute" (absolute contributions are indicated by colour intensities). "relative" (relative contributions are indicated by colour intensities). If set to "absolute" or "relative", points with zero contribution are displayed in white. The higher the contribution of a point, the closer the corresponding colour to the one specified by the col option.
col	Vector of length 2 specifying the colours of row and column point symbols, by default black for rows and red for columns. Colours can be entered in hexadecimal (e.g. "#FF0000"), rgb (e.g. rgb(1, 0, 0)) values or by R-name (e.g. "red").
pch	Vector of length 4 giving the type of points to be used for row active and supplementary, column active and supplementary points. See pchlist for a list of symbols.
labels	Vector of length two specifying if the plot should contain symbols only (0), labels only (1) or both symbols and labels (2). Setting labels to 2 results in the symbols being plotted at the coordinates and the labels with an offset.
collabels	Determines the format used for column labels, when the columns are labeled in the plot. "both" uses the factor names and level value, in the form "factor:level" "level" uses the factor level value only "factor" uses the factor name only
arrows	Vector of two logicals specifying if the plot should contain points (FALSE, default) or arrows (TRUE). First value sets the rows and the second value sets the columns.
xlab, ylab	Labels for horizontal and vertical axes. The default, "_auto_" means that the function auto-generates a label of the form Dimension X (xx.xx %)
...	Further arguments passed to plot and points .

Details

The function `plot.mjca` makes a two-dimensional map of the object created by `mjca` with respect to two selected dimensions. By default the scaling option of the map is "symmetric", that is the so-called *symmetric map*. In this map both the row and column points are scaled to have inertias (weighted variances) equal to the principal inertia (eigenvalue) along the principal axes, that is both rows and columns are in principal coordinates. Other options are as follows:

- "-rowprincipal" or "colprincipal" - these are the so-called *asymmetric maps*, with either rows in principal coordinates and columns in standard coordinates, or vice versa (also known as row-metric-preserving or column-metric-preserving respectively). These maps are biplots;
- "-sympbiplot" - this scales both rows and columns to have variances equal to the singular values (square roots of eigenvalues), which gives a symmetric biplot but does not preserve row or column metrics;
- "-rowgab" or "colgab" - these are asymmetric maps (see above) with rows (respectively, columns) in principal coordinates and columns (respectively, rows) in standard coordinates

multiplied by the mass of the corresponding point. These are also biplots and were proposed by Gabriel & Odoroff (1990);

- `"rowgreen"` or `"colgreen"` - these are similar to `"rowgab"` and `"colgab"` except that the points in standard coordinates are multiplied by the square root of the corresponding masses, giving reconstructions of the standardized residuals.

This function has options for sizing and shading the points. If the option `mass` is `TRUE` for a set of points, the size of the point symbol is proportional to the relative frequency (mass) of each point. If the option `contrib` is `"absolute"` or `"relative"` for a set of points, the colour intensity of the point symbol is proportional to the absolute contribution of the points to the planar display or, respectively, the quality of representation of the points in the display. To globally resize all the points (and text labels), use `par("cex"=)` before the plot.

Value

In addition to the side effect of producing the plot, the function invisibly returns the coordinates of the plotted points, a list of two components, with names `rows` and `cols`. These can be used to further annotate the plot using base R plotting functions.

Examples

```
data("wg93")

# A two-dimensional map with standard settings
plot(mjca(wg93[,1:4]))
```

Description

Graphical display of correspondence analysis in three dimensions

Usage

```
## S3 method for class 'ca'
plot3d(x, dim = c(1, 2, 3), map = "symmetric", what = c("all", "all"),
      contrib = c("none", "none"), col = c("#6666FF", "#FF6666"),
      labcol = c("#0000FF", "#FF0000"), pch = c(16, 1, 18, 9),
      labels = c(2, 2), sf = 0.00001, arrows = c(FALSE, FALSE),
      axiscol = "#333333", axislcol = "#333333",
      laboffset = list(x = 0, y = 0.075, z = 0.05), ...)
```

Arguments

x	Simple correspondence analysis object returned by <code>ca</code>
dim	Numerical vector of length 2 indicating the dimensions to plot
map	Character string specifying the map type. Allowed options include "symmetric" (default) "rowprincipal" "colprincipal" "symbiplot" "rowgab" "colgab" "rowgreen" "colgreen"
what	Vector of two character strings specifying the contents of the plot. First entry sets the rows and the second entry the columns. Allowed values are "none" (no points are displayed) "active" (only active points are displayed, default) "supplementary" (only supplementary points are displayed) "all" (all available points) The status (active or supplementary) is set in <code>ca</code> .
contrib	Vector of two character strings specifying if contributions (relative or absolute) should be indicated by different colour intensities. Available options are "none" (contributions are not indicated in the plot). "absolute" (absolute contributions are indicated by colour intensities). "relative" (relative contributions are indicated by colour intensities). If set to "absolute" or "relative", points with zero contribution are displayed in white. The higher the contribution of a point, the closer the corresponding colour to the one specified by the <code>col</code> option.
col	Vector of length 2 specifying the colours of row and column profiles. Colours can be entered in hexadecimal (e.g. "\#FF0000"), rgb (e.g. <code>rgb(1, 0, 0)</code>) values or by R-name (e.g. "red").
labcol	Vector of length 2 specifying the colours of row and column labels.
pch	Vector of length 2 giving the type of points to be used for rows and columns.
labels	Vector of length two specifying if the plot should contain symbols only (0), labels only (1) or both symbols and labels (2). Setting <code>labels</code> to 2 results in the symbols being plotted at the coordinates and the labels with an offset.
sf	A scaling factor for the volume of the 3d primitives.

arrows	Vector of two logicals specifying if the plot should contain points (FALSE, default) or arrows (TRUE). First value sets the rows and the second value sets the columns.
axiscol	Colour of the axis line.
axislcol	Colour of the axis labels.
laboffset	List with 3 slots specifying the label offset in x, y, and z direction.
...	Further arguments passed to the rgl functions.

`print.ca`*Printing ca objects*

Description

Printing method for correspondence analysis objects

Usage

```
## S3 method for class 'ca'
print(x, ...)
```

Arguments

x	Simple correspondence analysis object returned by ca
...	Further arguments are ignored

Details

The function `print.ca` gives the basic statistics of the `ca` object. First the eigenvalues (that is, principal inertias) and their percentages with respect to total inertia are printed. Then for the rows and columns respectively, the following are printed: the masses, chi-square distances of the points to the centroid (i.e., centroid of the active points), point inertias (for active points only) and principal coordinates on the first `nd` dimensions requested (default = 2 dimensions). The function [summary.ca](#) gives more detailed results about the inertia contributions of each point on each principal axis. For supplementary points, masses and inertias are not applicable.

See Also[ca](#)**Examples**

```
data("smoke")
print(ca(smoke))
```

print.mjca	<i>Printing mjca objects</i>
------------	------------------------------

Description

Printing method for multiple and joint correspondence analysis objects

Usage

```
## S3 method for class 'mjca'  
print(x, ...)
```

Arguments

x	Multiple or joint correspondence analysis object returned by mjca
...	Further arguments are ignored

Details

The function `print.mjca` gives the basic statistics of the `mjca` object. First the eigenvalues (that is, principal inertias) and their percentages with respect to total inertia are printed. Then for the rows and columns respectively, the following are printed: the masses, chi-square distances of the points to the centroid (i.e., centroid of the active points), point inertias (for active points only) and principal coordinates on the first `nd` dimensions requested (default = 2 dimensions). The function [summary.mjca](#) gives more detailed results about the inertia contributions of each point on each principal axis.

For supplementary points, masses and inertias are not applicable.

smoke	<i>Smoke dataset</i>
-------	----------------------

Description

Artificial dataset in Greenacre (1984)

Usage

```
data(smoke)
```

Format

Table containing 5 rows (staff group) and 4 columns (smoking categories), giving the frequencies of smoking categories in each staff group in a fictional organization.

References

Greenacre, M.J. (1984). *Theory and Applications of Correspondence Analysis*. London: Academic Press.

summary.ca	<i>Summarizing simple correspondence analysis</i>
------------	---

Description

Printed output summarizing the results of `ca`, including a scree-plot of the principal inertias and row and column contributions.

Usage

```
## S3 method for class 'ca'
summary(object, scree = TRUE, rows=TRUE, columns=TRUE, ...)
```

Arguments

object	Simple correspondence analysis object returned by <code>ca</code> .
scree	Logical flag specifying if a scree-plot should be included in the output.
rows	Logical: should row contribution summaries be included?
columns	Logical: should column contribution summaries be included?
...	Further arguments (ignored)

Details

The function `summary.ca` gives the detailed numerical results of the `ca` function. All the eigenvalues (principal inertias) are listed, their percentages with respect to total inertia, and a bar chart (also known as a scree plot). Then for the set of rows and columns a table of results is given in a standard format, where quantities are either multiplied by 1000 or expressed in permills (thousandths): the mass of each point (x1000), the quality of display in the solution subspace of `nd` dimensions, the inertia of the point (in permills of the total inertia), and then for each dimension of the solution the principal coordinate (x1000), the (relative) contribution COR of the principal axis to the point inertia (x1000) and the (absolute) contribution CTR of the point to the inertia of the axis (in permills of the principal inertia).

For supplementary points, masses, inertias and absolute contributions (CTR) are not applicable, but the relative contributions (COR) are valid as well as their sum over the set of chosen `nd` dimensions (QLT).

Examples

```
data("smoke")
summary(ca(smoke))
```

summary.mjca

Summarizing multiple and joint correspondence analysis

Description

Textual output summarizing the results of `mjca`, including a scree-plot of the principal inertias and row and column contributions.

Usage

```
## S3 method for class 'mjca'
summary(object, scree = TRUE, rows = FALSE, columns = TRUE, ...)
```

Arguments

<code>object</code>	Multiple or joint correspondence analysis object returned by <code>mjca</code> .
<code>scree</code>	Logical flag specifying if a scree-plot should be included in the output.
<code>rows</code>	Logical specifying whether the results for the rows should be included in the output (default = FALSE).
<code>columns</code>	Logical specifying whether the results for the columns should be included in the output (default = TRUE).
<code>...</code>	Further arguments (ignored)

Details

The function `summary.mjca` gives the detailed numerical results of the `mjca` function. All the eigenvalues (principal inertias) are listed, their percentages with respect to total inertia, and a bar chart (also known as a scree plot). Then for the set of rows and columns a table of results is given in a standard format, where quantities are either multiplied by 1000 or expressed in permills (thousandths): the mass of each point (x1000), the quality of display in the solution subspace of nd dimensions, the inertia of the point (in permills of the total inertia), and then for each dimension of the solution the principal coordinate (x1000), the (relative) contribution COR of the principal axis to the point inertia (x1000) and the (absolute) contribution CTR of the point to the inertia of the axis (in permills of the principal inertia).

For supplementary points, masses, inertias and absolute contributions (CTR) are not applicable, but the relative contributions (COR) are valid as well as their sum over the set of chosen nd dimensions (QLT).

Examples

```
data("wg93")
summary(mjca(wg93[,1:4]))
```

wg93

International Social Survey Program on Environment 1993 - western German sample

Description

This data frame contains records of four questions on attitude towards science with responses on a five-point scale (1=agree strongly to 5=disagree strongly) and three demographic variables (sex, age and education).

Usage

```
data(wg93)
```

Format

Data frame (871x7).
